

How to use Surge:

After creating the project folder & html file you will type surge into the terminal and then you will need to put your log in information. It will upload everything from that folder into surge to create the website.

Once you upload on surge you will have a URL so then you will need to type it into the website validator.w3.org

This website checks to make sure your code is good for the web. It will tell you your mistakes.

To create a CNAME file you will need to `type touch CNAME`

If you want to edit it you will need to `type: code CNAME` it will edit in VS code. So you open your CNAME file. Whatever your url is, you type it in the file and you save it. And then whenever you go back you use surge it will upload automatically. You won't need to type in the url each time. It will read this CNAME file and upload to that url automatically. CNAME basically tells it where to look.
